Acknowledgments

The Australian Oilseeds Federation would like to thank Graincorp Operations Limited, Viterra Ltd and the Grainpool Pty Ltd. for providing the canola samples from the 2011 harvest. The assistance from all those involved in the analysis of these samples and compilation of the book is greatly appreciated.

Introduction

Sample Analysis

Canola samples representing the 2011 harvest were received from the bulk handlers in New South Wales, South Australia, Victoria and Western Australia. These samples are representative of the seed collected at each of their receival points and have been taken to cumulatively represent the Australian harvest. The NSW DPI Australian Oils Research Laboratory has no control over the collection of the samples and all data given is based on the analysis of the samples provided.

Each sample was analysed for oil, protein and glucosinolate concentrations; fatty acid profiles and volumetric grain weights according to the standard AOF methods outlined in the methods section at the back of this book. The NSW DPI Australian Oils Research Laboratory in Wagga Wagga performed all analyses on the samples. Oil and glucosinolate concentrations are reported at 6% moisture in whole seed and protein is reported in oil-free meal at 10% moisture.

Weather Production Review

The Season

Weather and Production Review 2011

The 2011 Season

Similar to the 2010 season, the prospects of mediocre wheat prices combined with a firm price outlook for canola leading up to the start of the sowing period in 2011. This resulted in an increase in the area sown to canola in all growing districts except in West Australia where a small decrease occurred due to a dry start to the season and a lack of stored soil moisture.

Good summer rainfall across New South Wales and Victoria resulted in an excellent and timely start to the 2011 season. However, dry conditions delayed the start of sowing in Western Australia and in some districts in South Australia.

New South Wales: A second summer of above average rainfall following a wet spring resulted in excellent sub soil moisture levels across all districts at the start of the season. Although the majority of the crop was sown within the recommended sowing window some delays were experienced in sections of the north west of the state due to dry surface soil conditions and the south west due to some paddocks being too wet following the high summer rainfall & subsequent flooding. Unfortunately, an extended period of below average rain that began at the start of sowing slowed seedling emergence and impeded overall crop establishment and growth across most districts. Significant mice damage occurred in many seedling crops in the central and south western regions and extensive baiting was required to bring the mice under control. An estimated 12-15,000 ha of crop required resowing due to the impact of the mice. A range of insects including slugs, slaters and crickets caused moderate damage to some crops that had been sown into wetter paddocks in the southern areas of NSW.

Following the dry and cold winter conditions, good spring rainfall resulted in a rapid improvement in growth and overall crop development. The continuation of mild temperatures throughout spring produced a long flowering period and later than normal finish to the season with a subsequent positive impact on crops setting them up for high yields and oil levels.

Good windrowing and harvest conditions occurred across most of the state. However, late rain in parts of the south western region caused weather damage to some crops resulting in a down grading in quality due to low test weight. Likewise in the central western region about 5,000 ha was lost due to flooding of paddocks after crops had been windrowed.

Final estimated production for New South Wales for 2011 was a record 720,000 tonnes from a harvested area of 390,000 ha for an average yield of 1.85 t/ha, which was slightly below the record state average yield of 1.97 t/ha achieved in 2010. By comparison in the 2010 season, final production was estimated at 610,000 tonnes from a harvested area of 310,000 ha.

Victoria: Above average spring and summer rainfall resulting in full sub soil moisture profiles across all districts at the commencement of sowing.

Although sowing was able to commence on time, drying surface soil in the Wimmera and Mallee regions caused some delays to the completion of sowing or crops being sown dry. This also impacted on germination resulting in an initial patchy establishment in many crops. In parts of the

high rainfall Western Districts sowing was delayed due to many paddocks being too wet after the high summer-early autumn rain.

The mice problem experienced in NSW during crop establishment and early seedling growth also extended into Victoria with extensive baiting being required to bring them under control. In the eastern section of the Western Districts, 15% of crops required resowing whilst around 10% of crops required ‘hotspots’ in paddocks to be resown due to mice damage. Slugs and crickets also caused damage to many crops, particularly where stubble had been retained, in the higher rainfall districts.

Most districts experienced good rainfall and favourable growing conditions during spring which set crops up for above average yields and high oil levels. In the Mallee region the dry sowing and subsequent delayed germination of crops resulted in a reduced level of vegetative growth which encouraged a higher than usual level of direct heading at harvest time.

Final estimated production for Victoria for 2011 was 770,000 tonnes from a harvested area of 370,000 ha out of the 390,000 ha estimated to have been sown producing a yield of 2.08 t/ha. By comparison production figures for the 2010 season were 440,000 tonnes from a harvested area of 240,000 ha.

South Australia: Good surface soil moisture allowed sowing to take place on time in most districts with the Mallee and South East regions being the exceptions. Similar to the East Coast states, subsoil moisture was excellent in all districts; however variable rainfall and drying surface soil during the winter period delayed the ability of many crops to tap into this deeper moisture. Scattered areas across the state also experienced mice problems during crop establishment. Snails, slugs and earwigs also caused some problems in wetter areas.

Good spring rainfall combined with mild temperatures across all growing districts during flowering and pod fill which resulted in a good finish to the season in South Australia. As a consequence yields and oil levels were above average with the state producing its largest canola crop on record.

Final estimated production for South Australia for the 2011 season was 455,000 tonnes from a harvested area of 255,000 ha yielding 1.78t/ha. By comparison production in 2010 was 360,000 tonnes of seed from a harvested area of 200,000 ha.

Western Australia: In contrast to the other states, Western Australia experienced very dry conditions, with the first significant rain falling in most districts in late May, delaying the start of sowing, although many growers took the opportunity to dry sow some crops. A continuation of dry conditions in the central wheat belt reduced the area of canola planted in that region. For the crops that were sown, moderate falls of rain during July and August across most districts, combined with above average temperatures, boosted crop growth going into the spring and improved yield prospects. The normally reliable growing district around Esperance, which had experienced very dry winter conditions, responded to good falls of rain in September lifting yield prospects, although from a lower base level.

Although the harvest commenced slightly earlier than normal across Western Australia widespread storm rain caused some harvest delays but did not result in any significant crop damage.

The final production estimate for Western Australia for the 2011 season were 1,240,000 tonnes from a harvested area of 800,000 ha which was a record harvest for the state. The yield was 1.55 t/ha. By comparison production for the 2010 season was 705,000 tonnes of seed from a harvested area of 845,000 ha.

Insects and Diseases in 2011

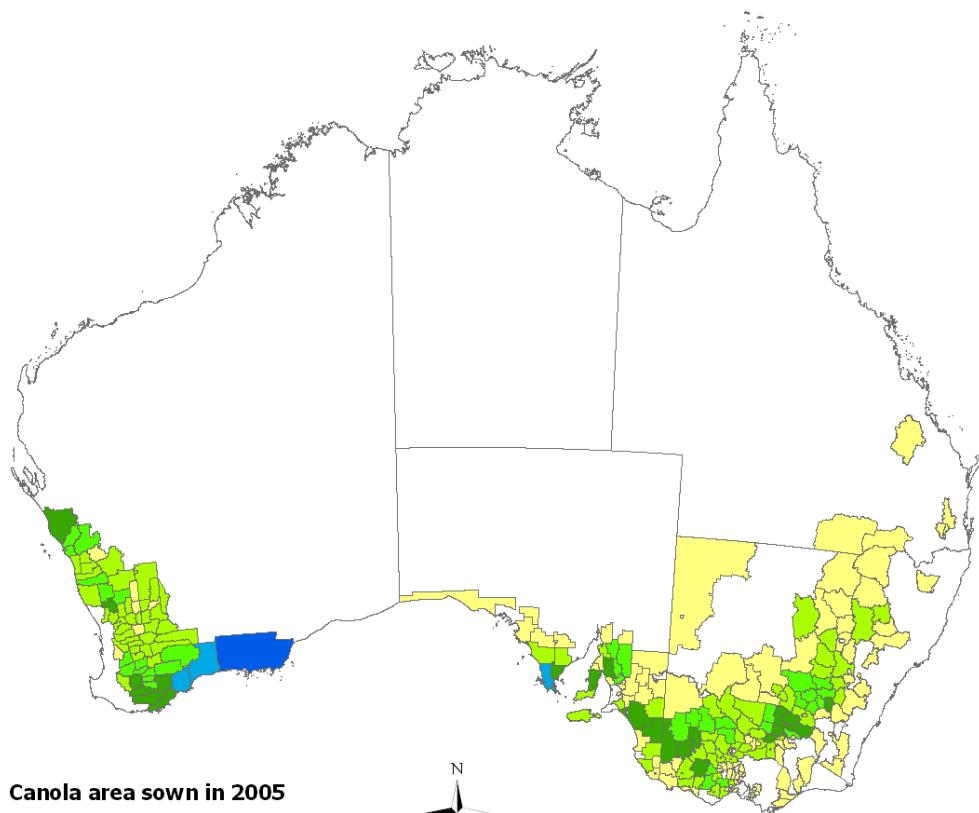

The impact of mice damage on newly sown and emerging crops was the most significant problem experienced by many growers in New South Wales, Victoria and South Australia. A large scale baiting program brought the problem under control and also prevented the worrying prospects of a large scale outbreak from occurring in the spring.

A range of insects including snails, slugs, crickets and earwigs also caused problems for growers in some regions across eastern Australia. In many cases the high level of stubble remaining on paddocks following on from a wet spring and summer period provided ideal conditions for these insects to breed as well as making it more difficult for growers to implement control measures.

Despite some reports of sclerotinia being present in some crops in southern NSW, the overall level of disease was low in all canola growing regions across Australia. However, reports of growers sowing consecutive crops of canola in the same paddock are a cause for concern for the whole industry because of the implications for the breakdown of current resistance levels in all canola varieties.

There is increasing interest in the production of High Oleic Low Linolenic (HOLL or Monola) varieties of canola for use by fast food companies/groups in the domestic market. The premium paid for these varieties over normal varieties will ensure an increased production in the future.

Yield

The 2011 canola harvest was a record breaking season. The national total production and the production for each of the states was the highest on record and the Victorian yield was also a record high. Of the 1,830,000 hectares planted a record breaking 1,815,000 hectares were harvested; this produced the largest harvest on record of 3,185,000 tonnes of canola.

The national yield of 1.75 t/ha was 0.43 t/ha more than 2010 and second only to the 1992 harvest of 1.90 t/ha. The yield varied from a state average of 1.55 t/ha in Western Australia to 2.08 t/ha in Victoria. The yields from all states were among the highest recorded. Victoria was 0.25 t/ha greater than the previous record of 1.83 t/ha from the 2010 season. Both New South Wales and South Australia were second only to the 2010 record high and Western Australia recorded its third highest yield behind the 2008 and 2007 harvests.

Table 1: Canola production in Australia by state 2011

State	Production (kilotonnes)	Area Harvested (kilohectares)	Average Yield (tonnes/hectare)
New South Wales	720	390	1.85

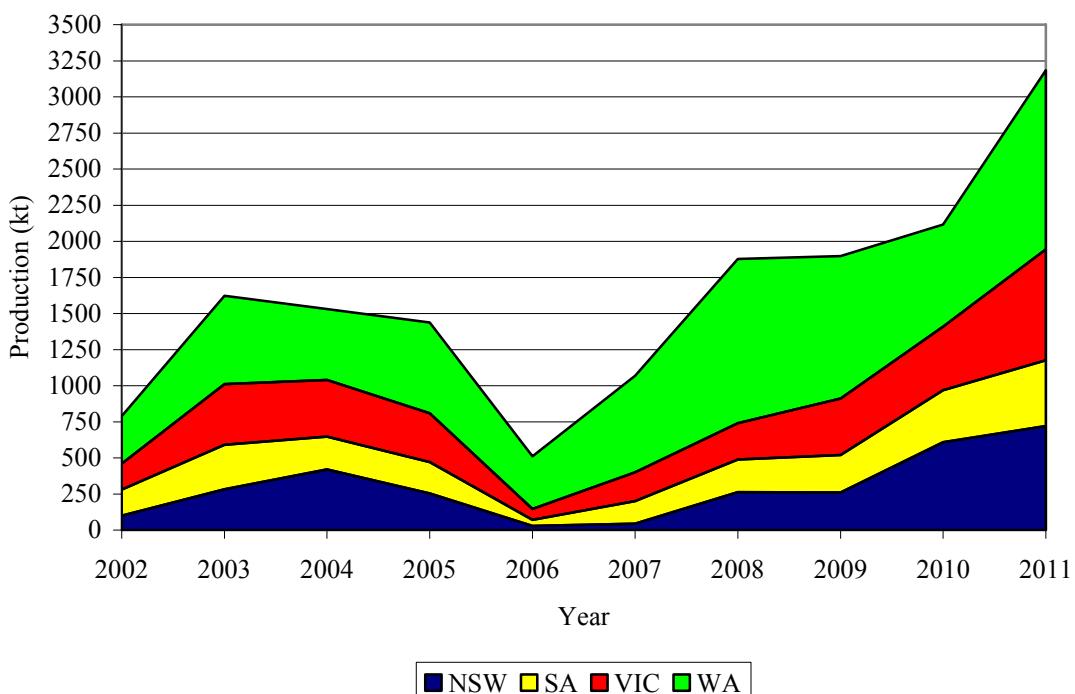

Figure 2: Canola Production in Australia 2002 – 2011

Australian Quality Parameter Summary

The mean regional and state values for all analyses for New South Wales, South Australia and Victoria were calculated on the basis of the tonnage each Site and Grade represents.

This information was not available for Western Australia, so the arithmetic mean instead of the weighted mean is reported.

The Australian mean values were calculated using the sum of the tonnages for each Site and Grade in New South Wales, South Australia and Victoria and the total tonnage for Western Australia.

However, due to tonnages being confidential information, no individual site tonnages can be reported.

Table 2: Average quality of Australian canola 2011

Quality Parameter	Australian Mean
Oil content, % in whole seed @ 6 % moisture	44.0
Protein content, % in oil-free meal @ 10 % moisture	37.9
Glucosinolates, µmoles/g in whole seed @ 6 % moisture	9

	kg/hL
Oleic acid concentration (C18:1), % in oil	61.8
Linoleic acid concentration (C18:2), % in oil	18.7
Linolenic acid concentration (C18:3), % in oil	10.4
Erucic acid concentration (C22:1), % in oil	0.2
Saturated fatty acid concentration, % in oil	7.2
Iodine Value	114.1

Oil Content

The average oil content for the 2011 harvest was 44.0 %. This was an increase of 1.1 % from the 2010 harvest and equal to the record high of 2007. Oil content ranged from a low of 40.7 % at Premer in New South Wales and York in Western Australia to a high of 47.2 % at Munglinup in Western Australia.

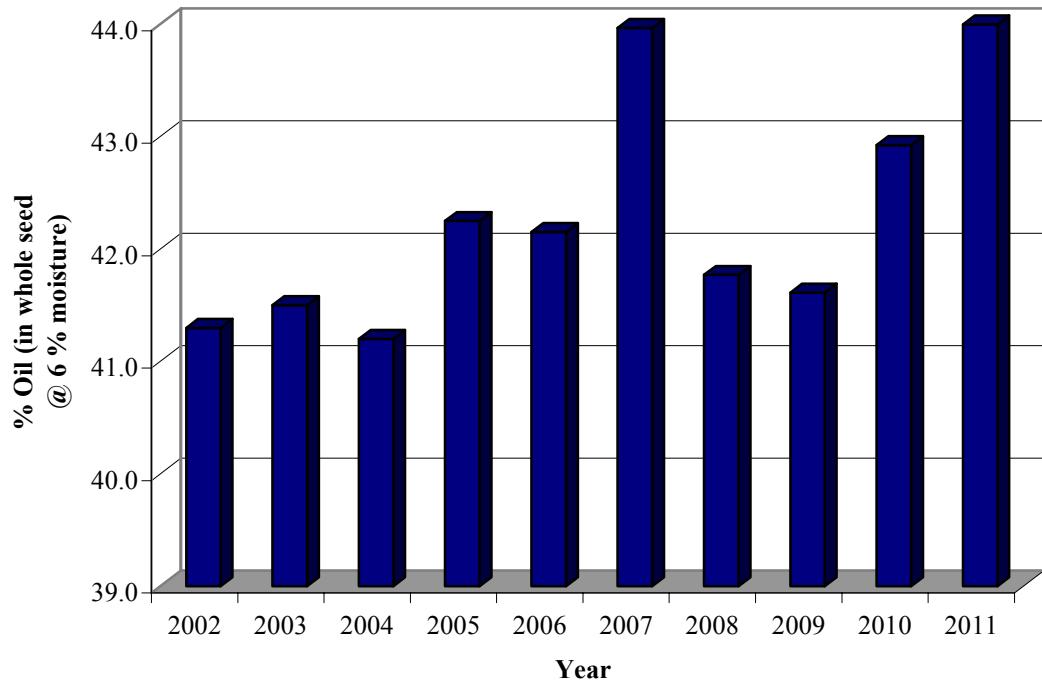

Figure 3: Average Australian oil content 2002 – 2011

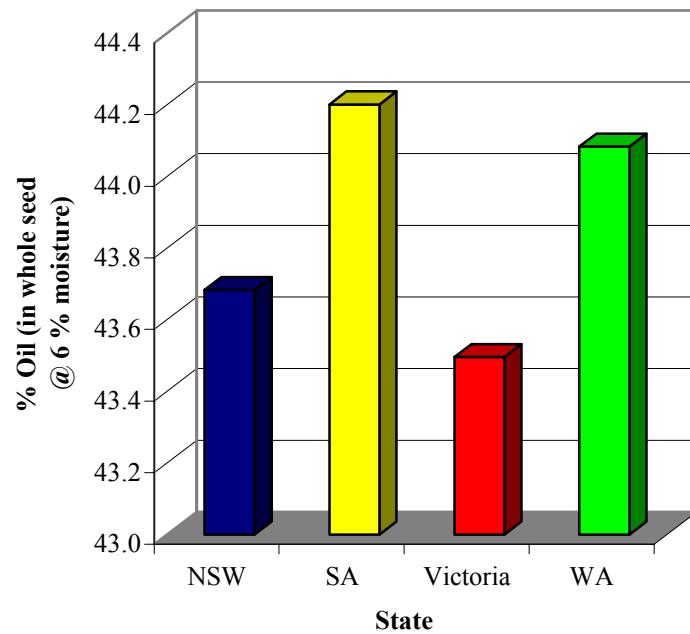

Figure 4: Average oil content by state 2011

Protein Content

The average protein content for the 2011 harvest was 37.9 % in oil free meal. This was a decrease of 2.0 % from the 2010 harvest and the lowest since 2005. Protein content ranged from 35.2 % at Ulamambri in New South Wales to 42.3 % at Nyngan in New South Wales.

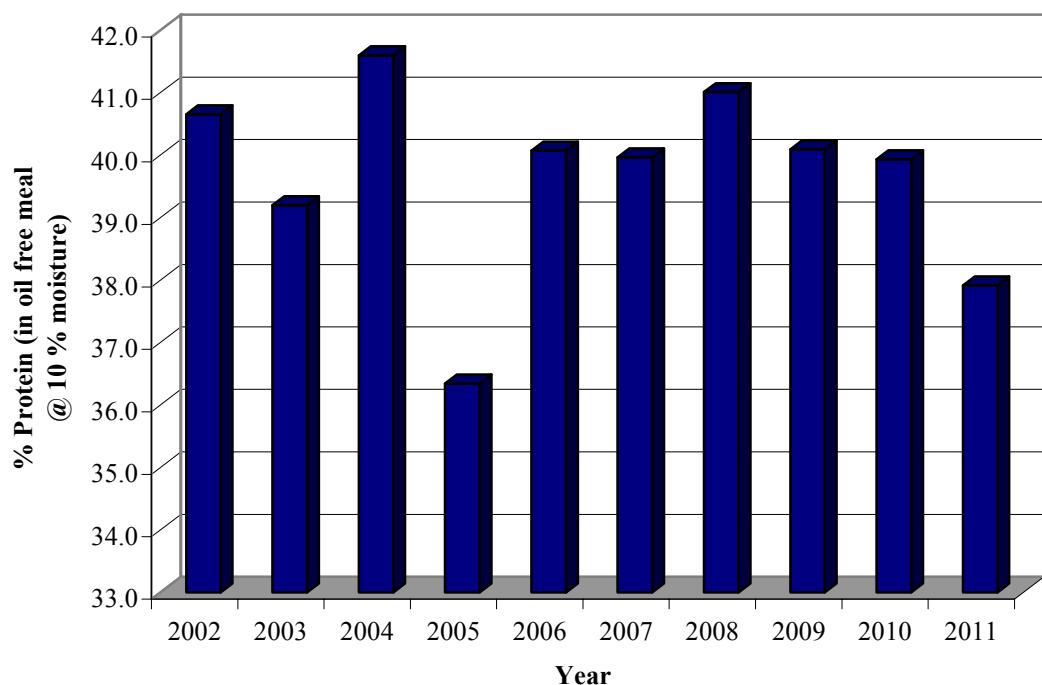

Figure 5: Average Australian protein content 2002 – 2011

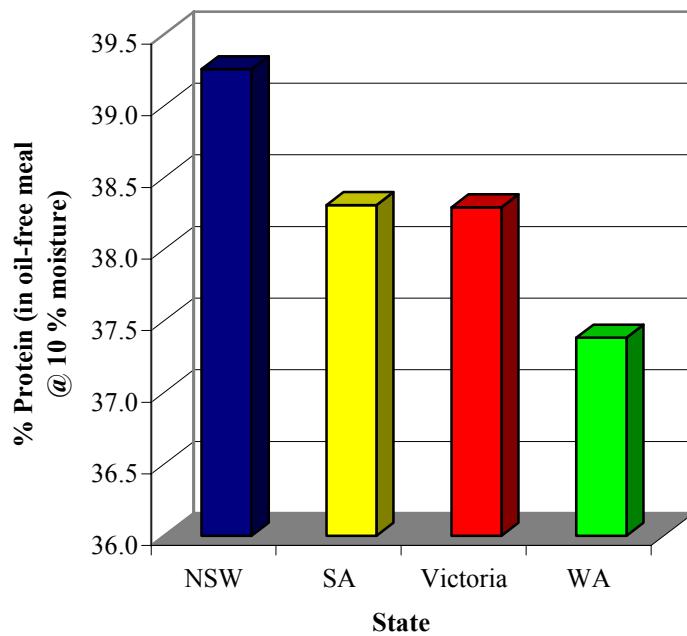

Figure 6: Average protein content by state 2011

Glucosinolate Concentration

The average glucosinolate content for the 2011 harvest was 9 µmoles/g. This was a decrease of 1 µmoles/g from the 2010 season. Glucosinolate content ranged from 6 µmoles/g at Greenhills and MGC in Western Australia to 14 µmoles/g at York in Western Australia.

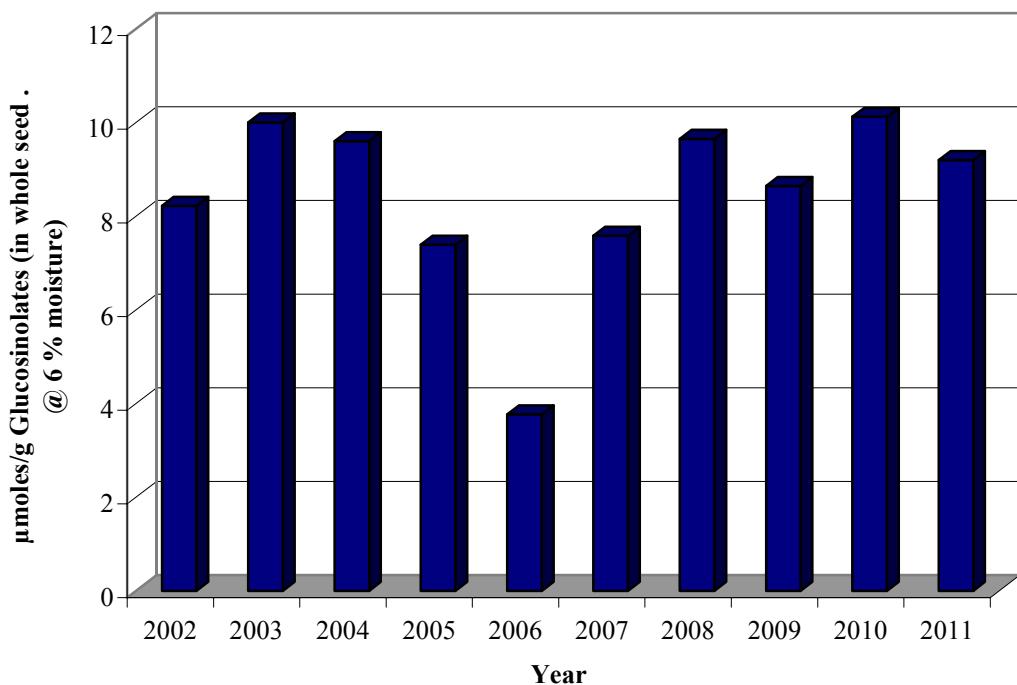

Figure 7: Average Australian glucosinolate content 2002 – 2011

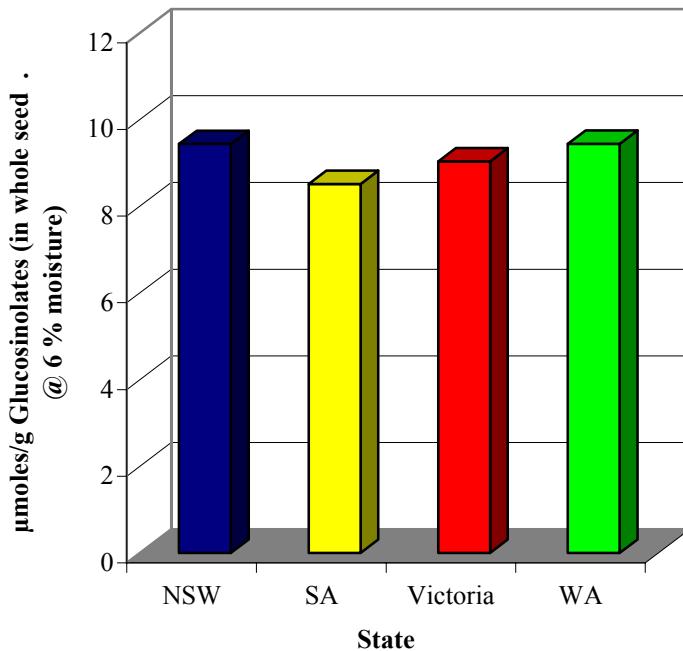

Figure 8: Average glucosinolate content by state 2011

Fatty Acid Composition

Oleic Acid

The average oleic acid (C18:1) concentration in the oil produced from the 2011 harvest was 61.8 %. This was 0.6 % higher than 2010 and the highest recorded since the inception of this book. The oleic concentration ranged from 58.1 % at Warracknabeal in Victoria to 69.5 % at Ulamambri in New South Wales.

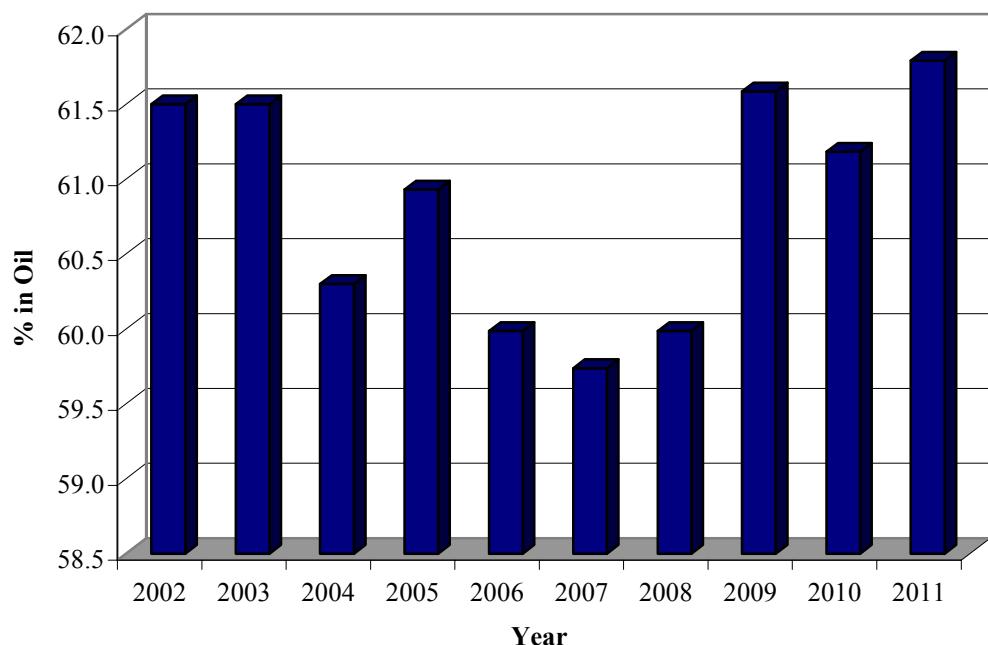

Figure 9: Average Australian oleic acid concentration in canola oil 2002 – 2011

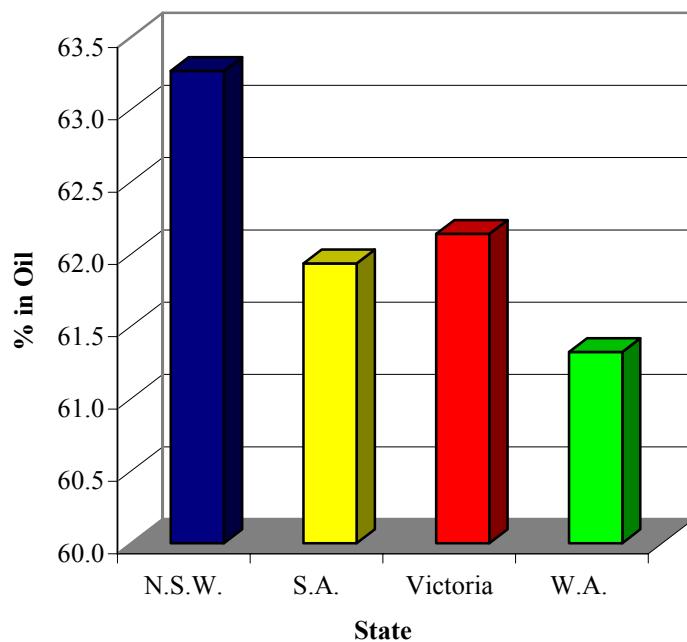

Figure 10: Average oleic acid concentration by state 2011

Linoleic Acid

The average linoleic acid (C18:2) concentration in oil produced from the 2011 harvest was 18.7 %. This was 0.7 % lower than 2010 and the second lowest in the eighteen year history of this book. The concentration ranged from 13.2 % at Ulamambri in New South Wales to 21.3 % at Warracknabeal in Victoria.

Linolenic Acid

The linolenic acid (C18:3) concentration remained constant at 10.4 % from the 2010 harvest. Linolenic acid concentrations ranged from 8.5 % at Culcairn and Temora in New South Wales to 12.2 % at Parilla in South Australia.

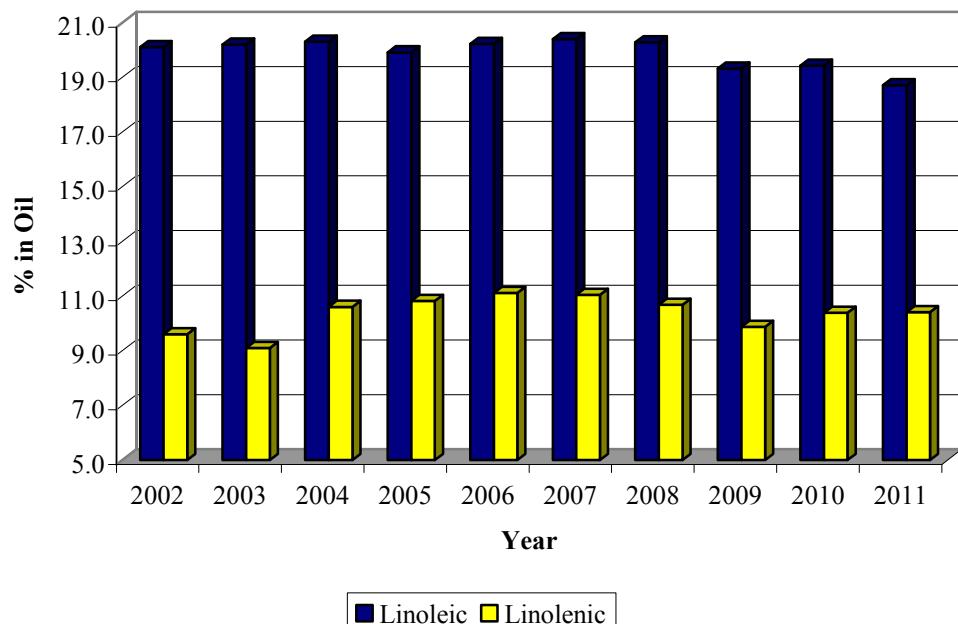

Figure 11: Average Australian linoleic acid and linolenic concentration in canola oil 2002 – 2011

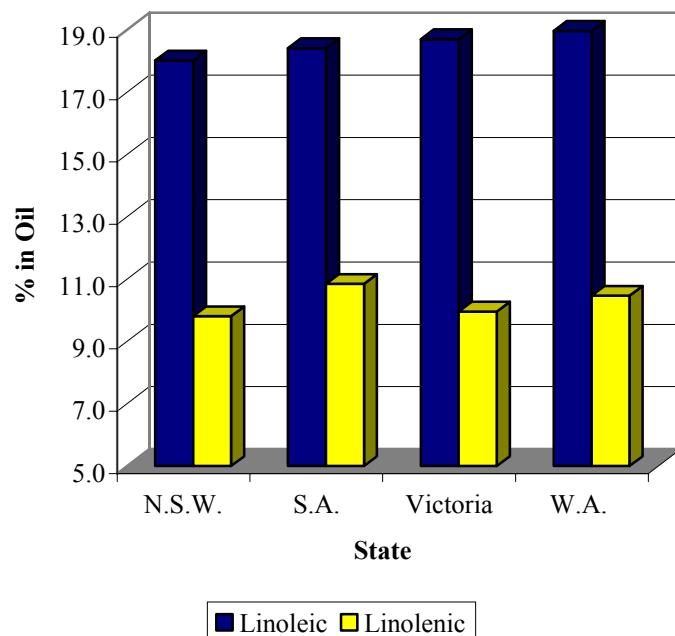

Figure 12: Average linoleic acid and linolenic acid concentration by state 2011

Saturated Fatty Acid

The average saturated fatty acid concentration was 7.2 %. This was a 0.2 % decrease from the 2010 harvest and the lowest since 2006. Saturated fatty acid concentration ranged from 6.8 % at Ungarra in South Australia and Munglinup in Western Australia to 8.0 % at Wangamong in New South Wales (considered a part of GrainCorp's Victorian operation) and York in South Australia.

Definitions

Canola is a term used to describe seed of the species *Brassica napus* or *Brassica campestris*, the oil component of which seed contains less than 2 % erucic acid (C22:1) and the solid (meal) component of which seed contains less than 30 micromoles of any one of, or any mixture of, 3-butetyl glucosinolate, 4-pentenyl glucosinolate, 2-hydroxy-3-butetyl glucosinolate and 2-hydroxy-4-pentenyl glucosinolate per gram of air-dry, oil-free solid as measured by the gas chromatographic method of the Canadian Grain Commission (Canola Council, Winnipeg, Manitoba, Canada).

The term Juncea Canola is used for mustard (*Brassica juncea*) varieties which have oil and meal quality similar to canola. Fatty acid profiles of the oil and the level of and types of glucosinolates in the meal all meet the quality specifications for canola.

Methods

Moisture Content:

Moisture is determined on whole seed using a 6500 near infrared (NIR) spectrometer calibrated using AOF 4-1.6: "Moisture Content of Oilseeds Oven Method". The moisture contents are used to convert the raw data for oil, protein and glucosinolates to the appropriate moisture content for reporting.

Oil Content:

Oil content is determined by NIR, calibrated from results obtained using method AOCS Am2-93 "Determination of Oil Content in Oilseeds". Oil is extracted from ground seed on either a Foss Soxtec™ 2050 or a Büchi B-811 Extraction System using hexane for four hours. The sample is reground and extracted for 2 hours. The sample is again ground and extracted for a further 2 hours. The results are reported as a percentage of the seed at 6 % moisture.

Protein Content:

Protein content is determined on whole seed by NIR, calibrated from samples analysed by the LECO elemental analyser using AOF 4-3.3: "Protein, Crude, of Meals (Combustion)". Results are reported as percent protein (Nitrogen x 6.25) and calculated to 10 % moisture in oil-free meal.

Glucosinolate Content:

Total glucosinolate concentration is determined by NIR, calibrated by method AOF 4-1.22: “Glucosinolate Content, Glucose Method, Canola and Rapeseed”. The method involves an enzymatic hydrolysis to release glucose followed by a colorimetric reaction and determination by a UV-Vis spectrophotometer. The method has compared favourably with the HPLC methodology of the AOCS with the added advantage of speed and economy. Results are reported as μ moles glucosinolates/gram whole seed at 6 % moisture.

Fatty Acid Composition:

Fatty acid composition involves methylation of fatty acids with a methanolic solution of potassium hydroxide. The method is based on IOC COI/T.20/Doc. No. 24 2001: “Preparation of the Fatty Acid Methyl Esters from Olive Oil and Olive-Pomace Oil”. The methyl esters are then separated on a gas chromatograph using a BPX70 capillary column. Fatty acids are reported as a percentage of the total fatty acids.

Iodine Values:

Iodine values are calculated from the fatty acid profile using AOF 4-2.14: “Iodine Value by Fatty Acid Composition”.

Volumetric Grain Weights:

Volumetric grain weights are measured using a Franklin chondrometer and reported as both pounds/bushel and kilograms/hectolitre.
